01

At a glance

EdgeCraft-StrikeCity turns trading on Strike into a place you can walk around. Every character in the city is driven by real data from Strike, and behind the city sits a complete product: agents that trade your own Strike account, a smarter way to choose whom to copy, and an agent that can run that copy for you.

Live
on Strike mainnet, with a full staging copy on Strike testnet

1
wallet signature to create an agent that trades your own Strike account

35
Strike endpoints in use, from builder connect to managed copies and live trades

389
real copies behind the Strike City score, re-tested every hour

0.20%
builder fee per execution, the project's revenue, approved by each user

174
automated tests, plus 244 real-browser checks per language

What you can do with it

- **Watch the agents and the traders, live.** Agents walk to the Signal Lab when a candle closes, to the Strike Exchange when they send an order and to a market's tower while they hold a position there. The traders people copy on Strike walk with their current copiers in a line behind them.
- **Start an agent with one signature.** Pick a strategy from the marketplace, design a character, and sign once. Strike's builder connect authorises the agent on your own account; your money never leaves Strike.
- **Choose whom to copy, with evidence.** The Copy Arena ranks every trader with a score built from what copying them actually did for the people who tried it.
- **Let your agent copy for you.** Sign a copy plan and your agent runs it on Strike's own copy trading, in a sub-account Strike creates for it, with Strike enforcing your stop-loss.
- **Read the news that moves your markets.** The News Tower scores headlines and checks them against Strike's price afterwards.
- **See Strike trade.** Every car on the streets is a real trade on Strike mainnet, green when the taker bought and red when they sold. Rest the mouse on one and it stops; press it to see the trade.

Why it matters for Strike

Every agent trade is volume through Strike's builder code, and every copy an agent starts brings money and copiers into Strike's own copy trading. Every user who joins arrives with their Strike account already working. Copy trading, which today lives in a leaderboard, becomes something people can see, compare and talk about. And the pieces line up with Strike's own 2026 roadmap: vaults, a marketplace for trading tools, new asset classes and a mobile app.

02

Why we built it

Strike already has the hard part: a fast exchange, builder codes, copy trading and an open API. What it did not have was a way to make all of that visible and easy to trust.

Trading happens behind numbers

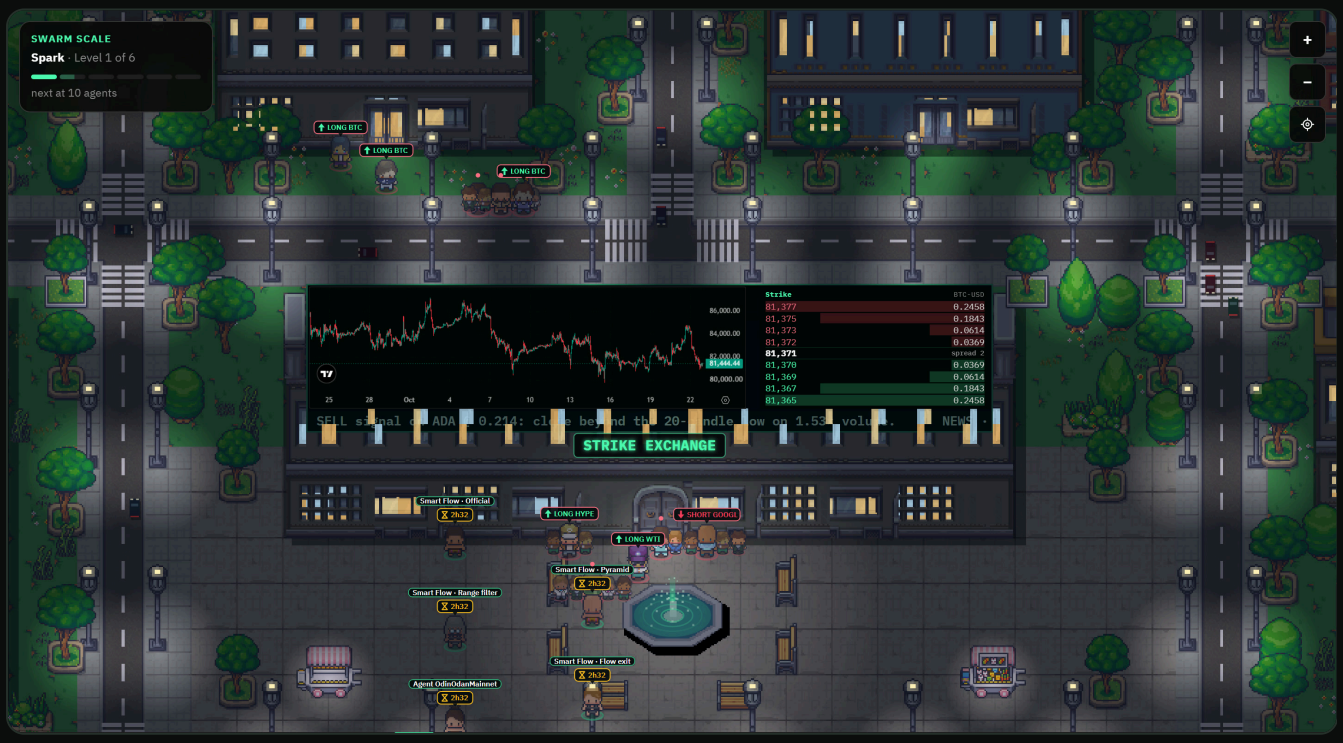

A trading bot is a process nobody sees. You check a balance and hope. When it does nothing for a day, you cannot tell whether it is broken or simply waiting for the right candle. We wanted every agent to be visible at all times, doing something that matches what it is really doing, with its reasons one click away.

Copy-trading leaderboards hide the outcome

Strike's copy trading lists traders with their returns and a copy score. What the list does not show is what happened to the people who copied them. Across the copies Strike has published, only about one in five ended in profit, and a trader's own return says surprisingly little about how their copiers did. So we measured it: every copy, before and after, and built a score from what actually predicted a good copy.

Starting should take one minute

Running a trading agent usually means API keys, servers and configuration files. On Strike it can be a single wallet signature, thanks to builder connect. We built the onboarding around that signature and made the review screen say, in plain words, exactly what the agent will be able to do and what it never will.

The Strike Exchange on a normal afternoon. The big screen shows Strike's live BTC order book; the characters with a bubble are agents and copied traders, each standing where its real state puts it.

03

A walk through the product

Six stops: the city, the strategy marketplace, your own agent, the Copy Arena, copying with your agent, and the News Tower. Every screenshot is the live product.

The city

The map is 96 by 64 tiles of streets, crossings and buildings, drawn with LimeZu's licensed pixel art. Characters find their way on foot with A* paths, and the camera can follow any of them. The rule is simple: nobody moves for show. A character walks because something real happened.

Building	An agent goes there when
Signal Lab	a candle closes and it analyses its markets
BTC, ETH and SOL towers, Alt Row	it holds a position in that market
Strike Exchange	it sends an order or a signal fires
Risk Office	the risk engine checks or refuses a signal
Liquidation Alley · Funding Cafe	a trade closed at its stop · by its exit rule
News Tower	the news reading of a market it trades changes level
Copy Arena	it copies a trader who is holding nothing right now
Agent Homes	it is paused, stopped, or waiting for a first deposit

The city also carries Strike's market, read live from Strike: prices on each tower, the order book on the Exchange's screen, the fountain's colour following BTC funding, weather that turns stormy when BTC moves hard, all 33 of Strike's markets in the Markets panel, and the traffic. **Every car on the streets is a real trade on Strike mainnet**: green when the taker bought, red when they sold, a truck from 5,000 $. A car stops under the mouse with a light outline, and pressing it shows the market, side, size, price and how long ago it happened.

Each agent has a personality, which sets the voice of its card, and a trade (chartist, reporter, tape reader, risk keeper) whose building it visits in shifts, showing the real data it reads there. Neither ever changes how it trades. On production the top bar and Ranks count real accounts only, with the paper agents that test the strategies ranked on their own; staging counts both.

The strategy marketplace

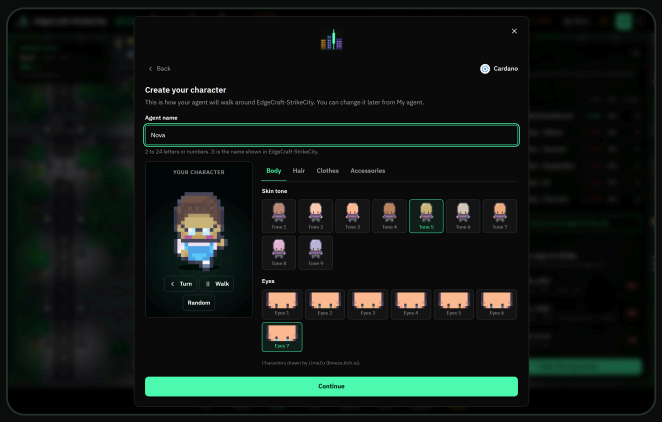

The landing page is a catalogue of strategies. Each one shows its rules, its full backtest after every cost and the risk it allows, and has a page of its own. One registry feeds the catalogue, the onboarding, the server and the agents' host, so a new strategy is added as data and shows up everywhere at once. Each entry already has room for a creator and a revenue share, which is how third-party strategies will join.

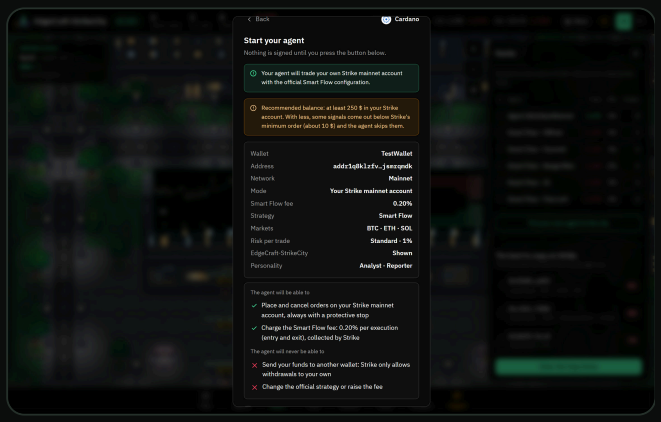

The two live strategies, Smart Flow and Smart Flow Pyramid, with their backtest figures at the default 1 % risk.

Your agent in one signature

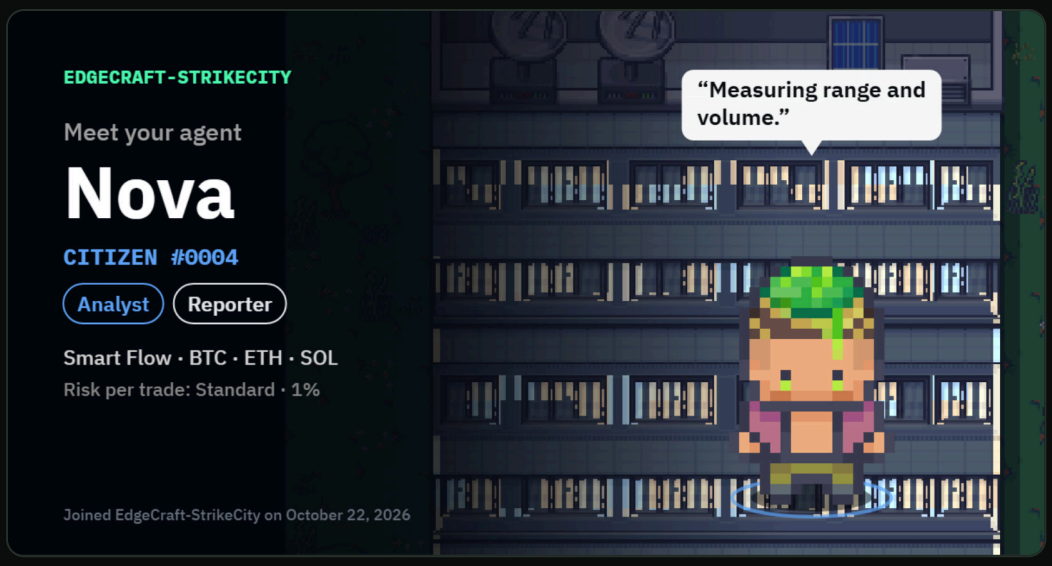

Creating an agent takes a minute. You design a character, answer five quick questions that give it a personality, pick its trade, then a strategy, markets and risk. The review screen lists everything, including the 0.20 % fee and what the agent can and cannot do. One signature later, Strike has authorised an API wallet for the agent on your own account, and the agent is walking around the city.

The character creator, built on LimeZu's generator.

The review: nothing is signed until you press the button.

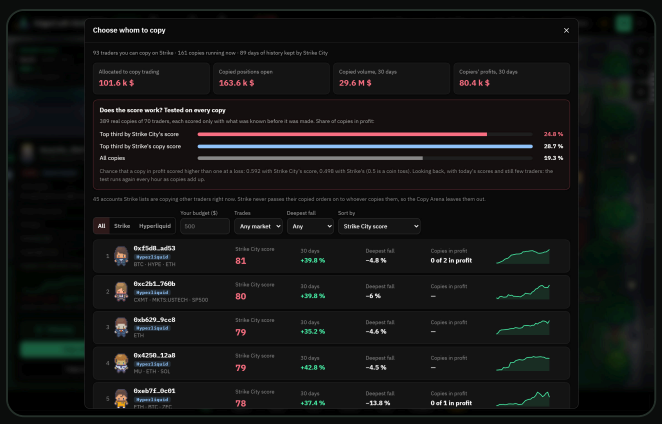

The last step: a card to save or share, with the agent's citizen number, personality, trade and strategy.

The Copy Arena

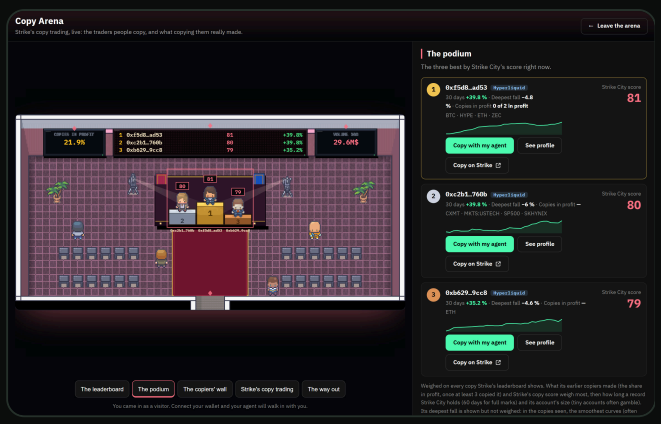

The traders people copy on Strike live in the city too, with a pink ring and their score over their head. They walk to the tower of their biggest position, run to the Exchange when they open, close or flip, and wait at the Copy Arena's door while they hold nothing. Behind each one walk the people copying them right now. Click one and you see what they hold, how copying them went for everyone who tried, and two ways to copy them.

A Hyperliquid trader copied through Strike, long HYPE, standing at the Exchange with the two people copying them. The card separates who copies them now from every copy they ever had.

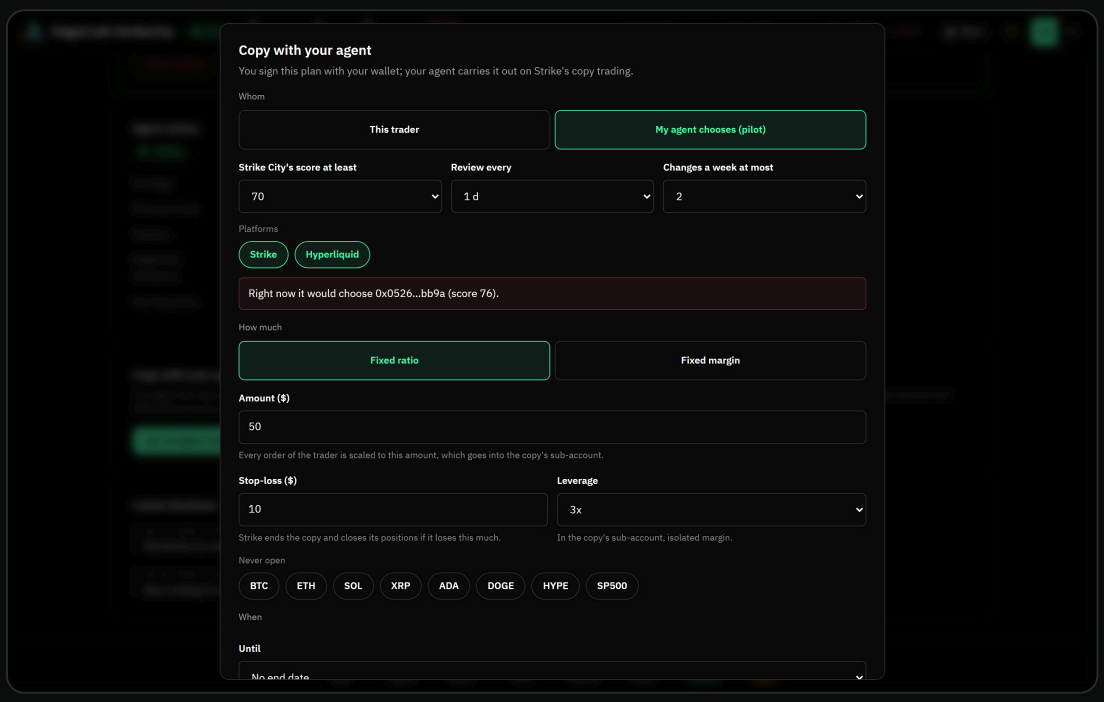

Choosing whom to copy: Strike's totals, the score's live test and every trader with what matters.

Inside the arena: the podium, the LED leaderboard and Strike's copy-trading totals.

Copy with your agent

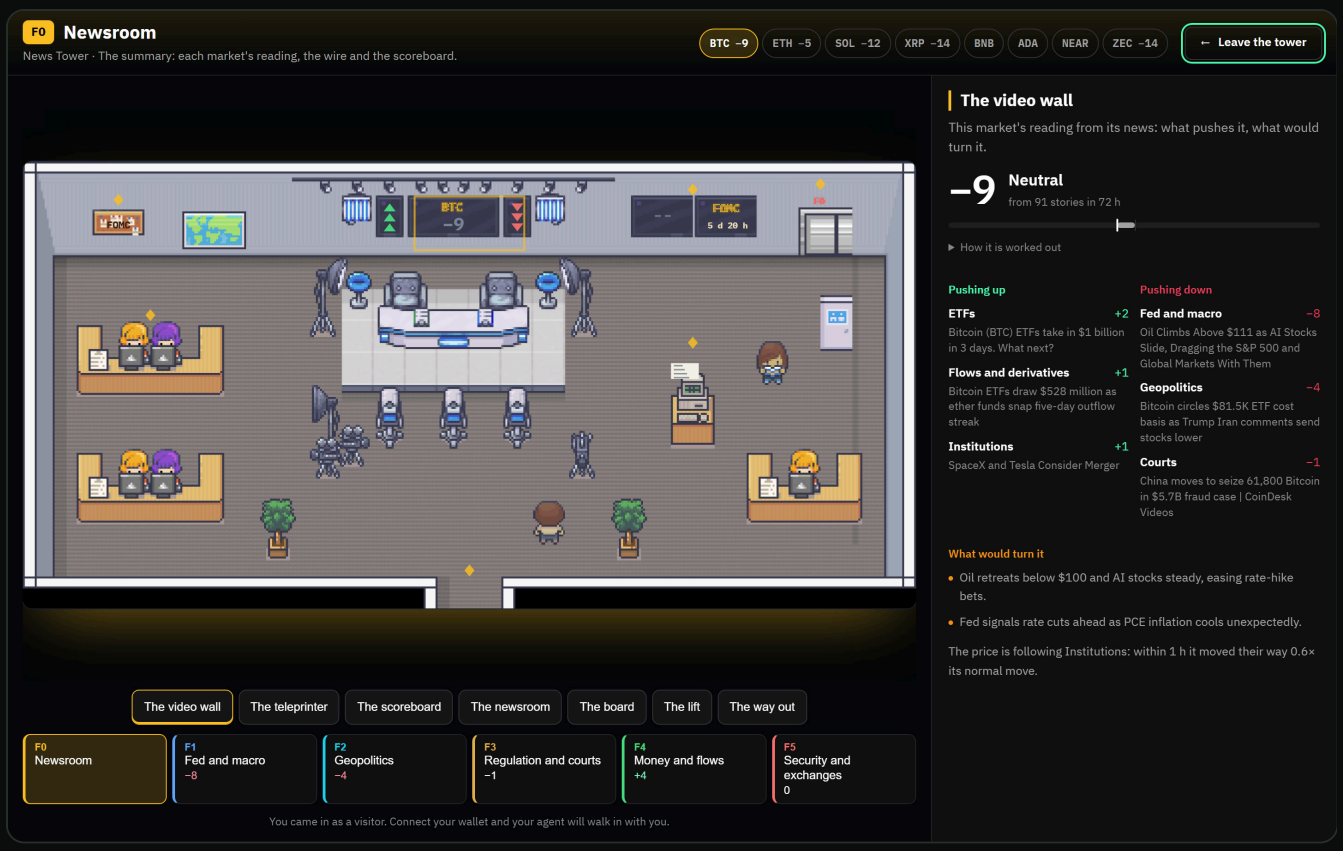

From any trader, or from "My agent", you can hand the copying to your agent. Choose one trader, or let the agent choose by your rules: a minimum score, the platforms you accept, how often it reviews its choice and how many changes it may make in a week. Then the amount, a stop-loss, the leverage, markets it must never open and an end date. You sign the whole plan in plain words, and your agent carries it out on Strike's copy trading, in a sub-account that Strike creates and funds for that copy. Strike enforces the stop-loss on its side.

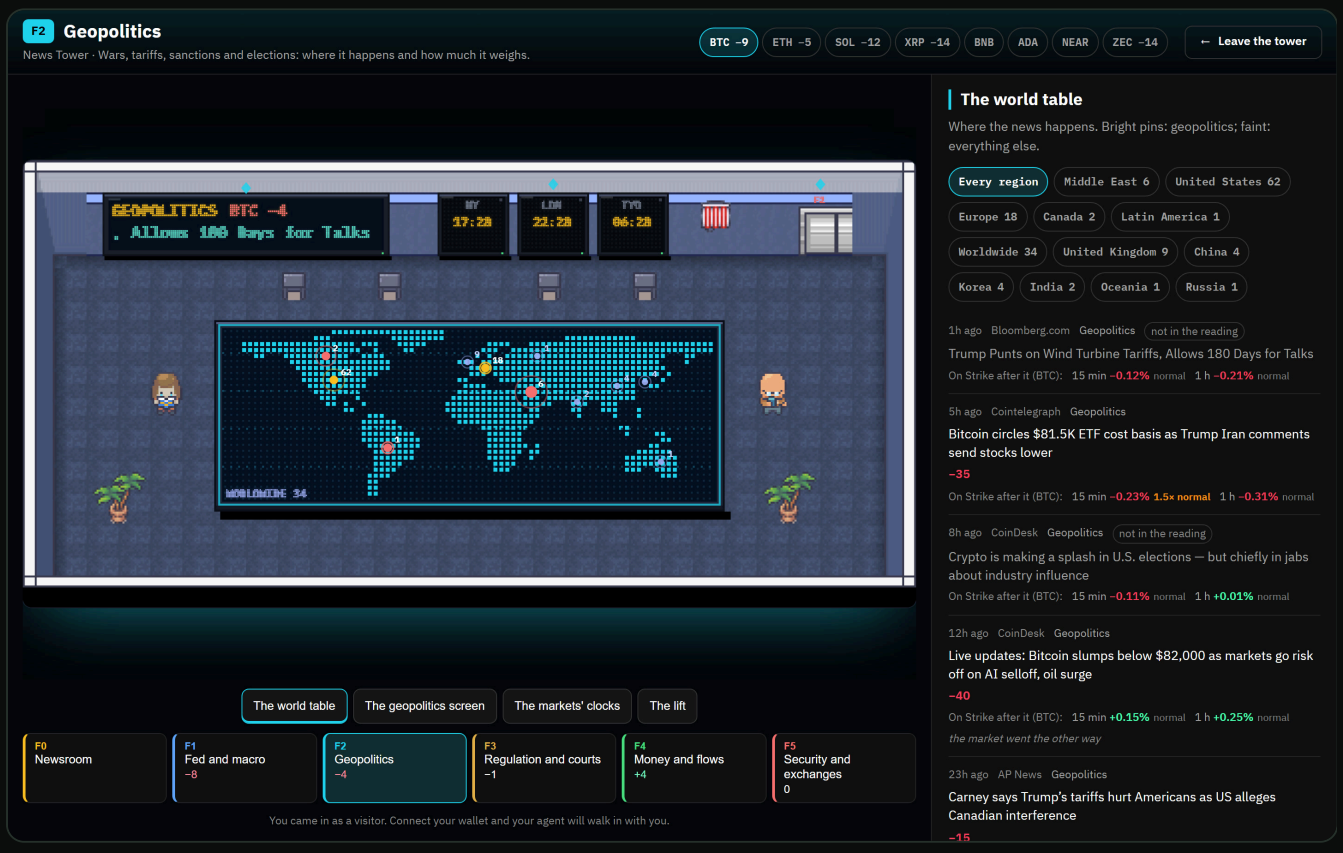

A copy plan in pilot mode. The box tells you whom the agent would choose right now with these rules.

The News Tower

Six floors of the news that moves crypto: the newsroom, Fed and macro, geopolitics, regulation and courts, money and flows, security and exchanges. Headlines come from official sources and tier-one outlets, a model scores each one on a fixed scale, each story counts once however many outlets carry it, and the reaction is measured on Strike's mark price afterwards. Your agent walks in with you, takes the lift and goes to whatever you choose to read. When a market's reading changes level, the agents trading it come to read it too. They never trade on news.

The newsroom: BTC's reading, what pushes it up and down, and what would turn it, with the floors of the tower along the bottom.

The geopolitics floor: the world table with stories pinned by region, and every story that counts in the reading.

04

Built on Strike

Strike is the venue for everything here, not a data source on the side. We use 35 of its endpoints in five areas, on mainnet and testnet, and fourteen of them were integrated during the hackathon: the whole of Strike's copy trading, and Strike's live trades.

Five integrations at a glance

Area	Endpoints	Called by	What it gives users and Strike
Builder connect and builder code	2 + header	the site's Functions	An agent on your own Strike account with one signature; 0.20 % of every execution to the builder
Trading API v2	16	every agent, on the host	Entries with their stop attached, exits, leverage that fits the margin, results that leave deposits out
Copy trading	13	the collector and the copy pilot	The Copy Arena, the Strike City score, and managed copies your agent runs in sub-accounts Strike creates
Market data	3 more (6)	the browser; the news service	Strike's market drawn live: prices, order book, funding, all 33 markets, every trade as a car, news reactions
Links and checks	1 more	everyone; our releases	"Copy on Strike" on every trader, and proof before each release that Strike answers as the client expects
Total	**35**		Mainnet and testnet, the same code

The map on the next page shows every one of them, who calls it and what for, and what Strike gets back.

Strike Finance

35 endpoints in use · five integrations · mainnet and testnet

1 Builder connect and builder code

called by the site's Functions, at onboarding

`POST /auth/builder/request-signature`	message
`POST /auth/builder/verify-signature`	authorise
`X-Builder-Fee-Bps: 20`	on every order

One wallet signature creates an agent on the user's own Strike account. Before saving anything, the site checks that Strike linked exactly our key, our builder code SmartFlowAgent-EdgeCraft and 20 bps. If anything differs, the key is burnt and the attempt is recorded.

Your wallet signs once → **Strike** links an API wallet → **Your agent** trades your account

Revenue: 0.20 % per execution, credited by Strike to the builder. Funds never leave the user's account, and the user approves the fee in Strike's own message.

2 Trading API v2

called by every agent on the host · Ed25519-signed

`GET /v2/time`	signing clock
`GET /v2/markets`	limits, sizes
`GET /v2/fee-tiers`	fees
`GET /price/v2/ticker/bookTicker`	executable price
`GET /price/v2/depth`	book impact
`GET /price/v2/premiumIndex`	mark price, stops
`GET /v2/account`	balance, margin
`GET /v2/positions`	positions
`GET /v2/openOrders`	open orders
`GET /v2/order`	look up before a retry
`POST /v2/order/strategy`	entry with its stop
`POST /v2/order`	stop move, exit
`DELETE /v2/order/cancel`	old stop
`POST /v2/leverage`	fits the margin
`GET /v2/history/fill`	fills, results
`GET /v2/history/transaction`	deposits kept out

Every order-creating request carries the builder fee, so each execution is credited to our builder code.

3 Copy trading

called by the collector (read only) and the copy pilot

`GET /v2/copy/discover`	traders to copy
`GET /v2/copy/leaderboard`	every copy, its end
`GET /v2/copy/subscriptions`	who copies whom
`GET /stat/v1/dashboard/copy-trading-*`	7 series
`POST /v2/copy/subscribe`	start a copy
`PATCH /v2/copy/subscribe/{id}`	change limits
`DELETE /v2/copy/subscribe/{id}`	stop it
`GET /v2/copy/subscriptions?scope=all`	status

Collector: no keys, history kept beyond Strike's 30 days. Pilot: Strike creates and funds a sub-account for each copy, and enforces its stop-loss on Strike's side. Traders' names, badges and positions: /v2/account and /v2/positions; Hyperliquid's public API for its traders.

4 Market data, live in the city

read straight from the browser (news: on the host)

`GET /price/v2/ticker/24hr`	towers, top bar
`GET /v2/markets`	all 33 markets
`GET /price/v2/premiumIndex`	the fountain
`GET /price/v2/depth`	Exchange screen
`GET /price/v2/trades`	the cars
`GET /price/v2/klines`	news reactions

Every car in the city is a real trade on Strike, green when the taker bought, red when they sold. If Strike cannot be reached, the city says so and shows Binance prices for display only; agents never trade on them.

5 Into Strike's app, and our checks

links for everyone · checks before every release

`Copy on Strike`	a trader's portfolio
`Builder codes`	from the landing
`smartflow strike-check`	public formats
`smartflow auth-check`	signed reads
`GET /v2/sub-accounts`	in auth-check
`testnet order probe`	brackets, cancel-all
`mainnet test trade`	loop with the fee

What Strike gets back

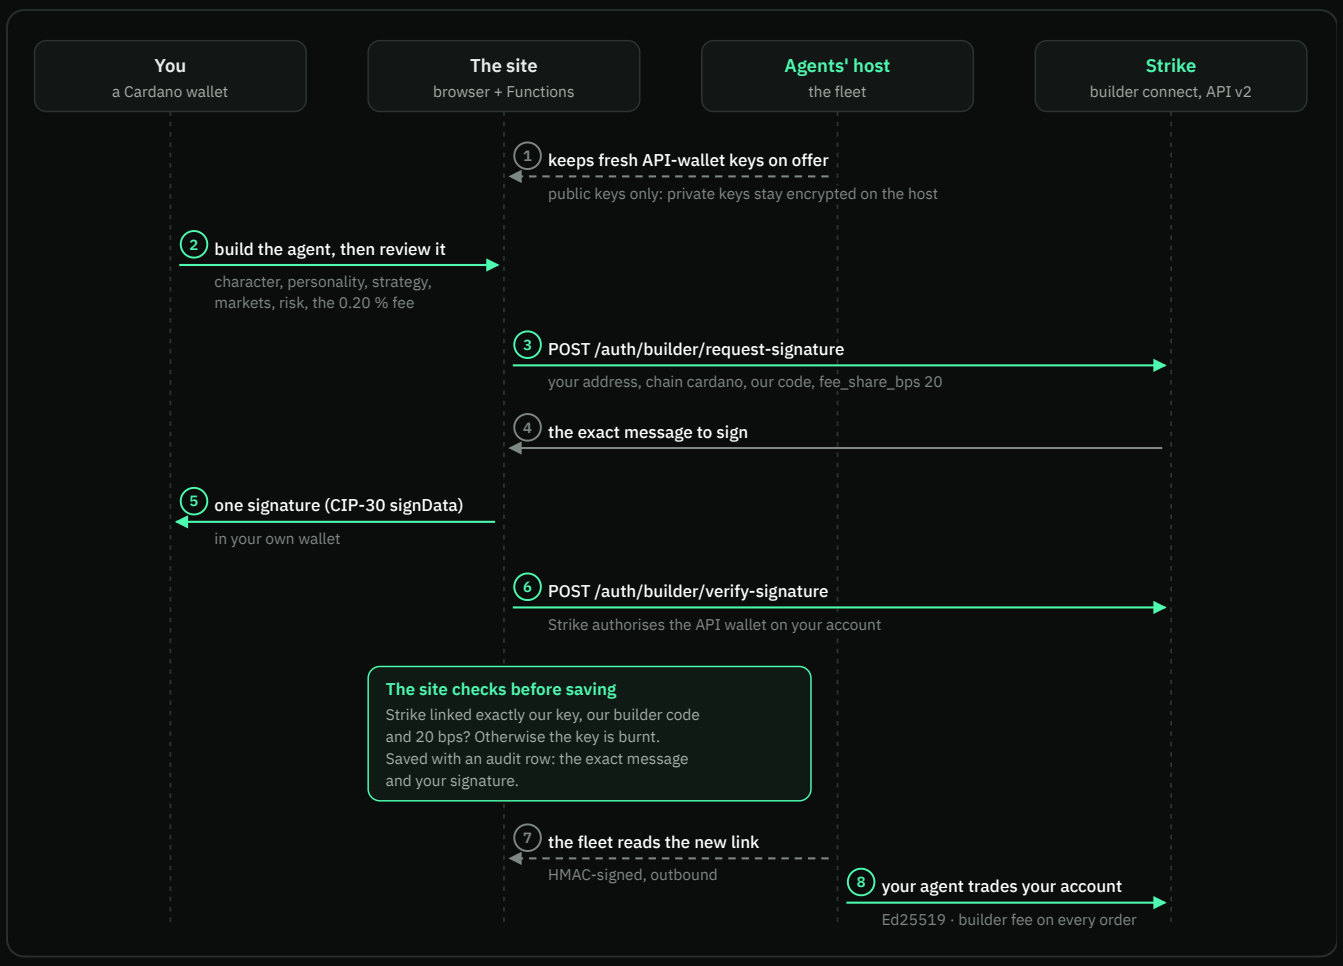

from every user and every agent

- Volume and fees through the builder code, on every execution of every agent
- Money and copiers for Strike's copy trading
- New users from Cardano wallets, trading from their first minute
- A measured way to choose whom to copy
- Open data: /api/copy and /api/city

Onboarding through builder connect

The site reserves a fresh API-wallet key that was generated on our host, asks Strike for the message to sign (`POST /auth/builder/request-signature`), lets the user's Cardano wallet sign it, and sends the signature back (`POST /auth/builder/verify-signature`). Before saving anything it checks that Strike linked exactly our key, our builder code `SmartFlowAgent-EdgeCraft` and our 20 bp fee. If anything differs, the key

is burnt and the attempt is recorded. The same signature proves the user owns the wallet, so creating an agent takes one signature in total.

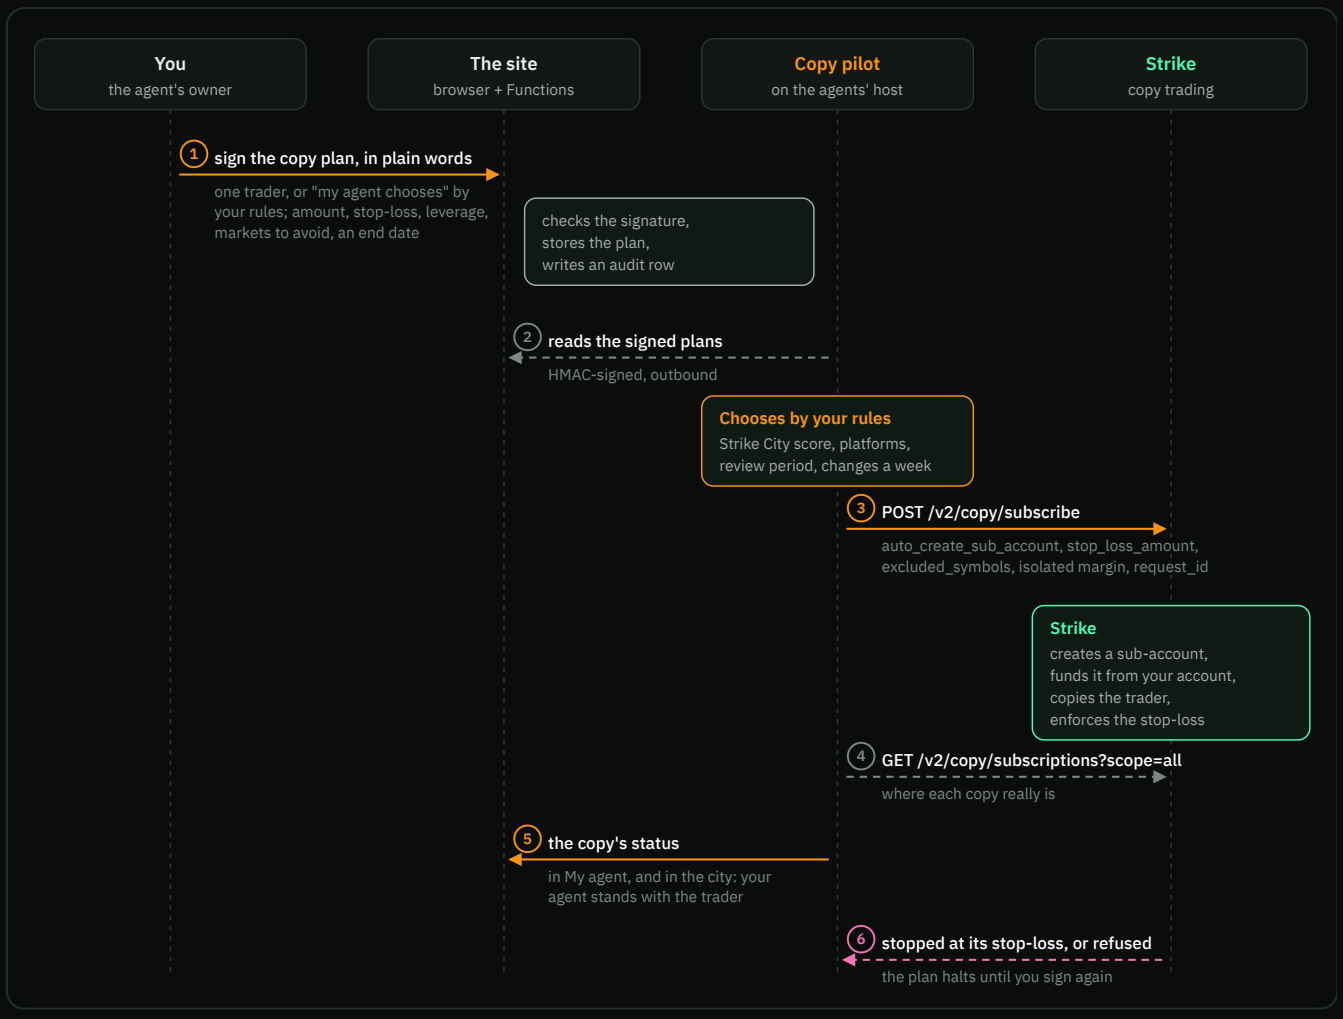

Trading

What for	Endpoints
Server time for signing	`GET /v2/time`
Markets, limits and fees	`GET /v2/markets` · `GET /v2/fee-tiers`
Executable prices and book impact	`GET /price/v2/ticker/bookTicker` · `GET /price/v2/depth`
Mark price for valuation and stops	`GET /price/v2/premiumIndex`
Account state	`GET /v2/account` · `GET /v2/positions` · `GET /v2/openOrders`
Idempotent retries	`GET /v2/order` by `client_order_id`
Entries with their stop attached	`POST /v2/order/strategy` (limit IOC with its `sl_order`)
Moving the stop, exiting	`DELETE /v2/order/cancel` · `POST /v2/order` (reduce-only stop on mark, reduce-only exit)
Leverage that fits the margin	`POST /v2/leverage`
Results that leave deposits out	`GET /v2/history/fill` · `GET /v2/history/transaction`

Every order-creating request carries `X-Builder-Fee-Bps: 20`, so each execution is credited to our builder code. A test trade from "My agent" runs the whole loop on the user's own account: Strike's minimum order with its stop, two minutes, then closed.

Copy trading

The collector holds no keys and keeps the history beyond the 30 days Strike's API returns. The copy pilot carries out each owner's signed plan with that owner's API wallet: Strike creates and funds a sub-account for each copy and enforces its stop-loss, and a copy Strike stopped or refused halts the plan until the owner signs again.

What for	Endpoints
Traders to copy, on Strike and Hyperliquid	`GET /v2/copy/discover`
Every copy and how it went	`GET /v2/copy/leaderboard` (active, stopped, liquidated)
Names, badges, sub-accounts, who copies whom	`GET /v2/account` · `GET /v2/copy/subscriptions`
Traders' open positions	`GET /v2/positions` · Hyperliquid `clearinghouseState`
Strike's copy-trading totals	`GET /stat/v1/dashboard/copy-trading-summary` and six daily series

Start a managed copy	`POST /v2/copy/subscribe` with `auto_create_sub_account`, `source_account_id`, stop-loss, excluded symbols, isolated margin, idempotent `request_id`
Change or stop a copy	`PATCH` / `DELETE /v2/copy/subscribe/{id}`
Where each copy really is	`GET /v2/copy/subscriptions?scope=all`

Market data, links and checks

- **In the city, read straight from the browser:** `GET /price/v2/ticker/24hr` on the towers and the top bar, `/v2/markets` for all 33 markets with their names and maximum leverage, `/price/v2/depth` on the big screen, `/price/v2/premiumIndex` on the fountain, and `/price/v2/trades` for the cars: BTC and the busiest markets in turn every 15 seconds, so every car is a trade that really happened on Strike.
- **Behind the news:** Strike's 1-minute mark candles (`/price/v2/klines`) measure every headline's reaction.
- **Into Strike's app:** every trader card links to that trader's public portfolio on Strike, where anyone can copy them by hand.
- **Checking our side:** `smartflow strike-check` and `auth-check` (including `GET /v2/sub-accounts`), plus order-mechanics probes on testnet and a full test-trade loop on mainnet.

> **Confirmed with Strike's team.** Before going live we asked Strike's team our open questions (19 October). The agents follow the answers: the builder fee is charged per fill and goes entirely to the builder, a fill without the fee header pays none, stop and take-profit legs inherit the code of their order, builder codes work on testnet, builder-connect API wallets do not expire, and `client_order_id` is not unique, so retries are made idempotent on our side.

05

The Strike City score

A copy-trading score is only useful if it says something about the next copy. So we built ours from what happened to real copies, and we test it again every hour, in public.

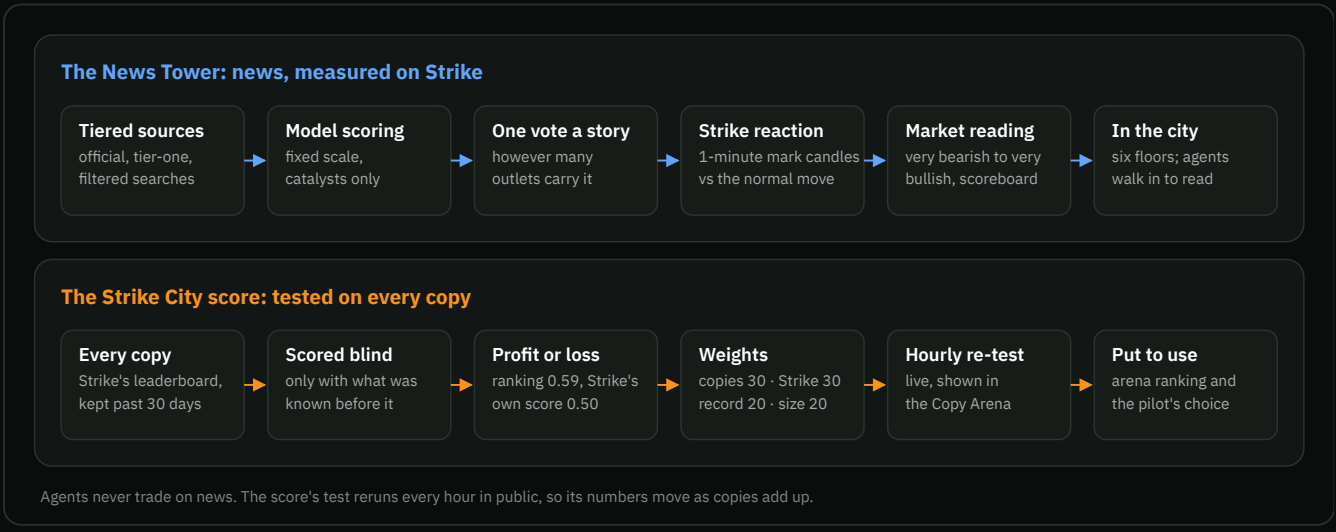

What goes into it

Part	Weight	Why
Share of earlier copies that ended in profit	30 %	The strongest predictor we found, counted once a trader has at least three copies
Strike's own copy score	30 %	It carries information Strike sees and we do not
Track record kept by Strike City	20 %	Full marks at 60 days; the collector keeps history beyond Strike's 30
Account size	20 %	Tiny accounts often gamble
Deepest fall of the PnL	shown	Shown on every profile but not weighted: smooth curves, often market makers, were the hardest to copy

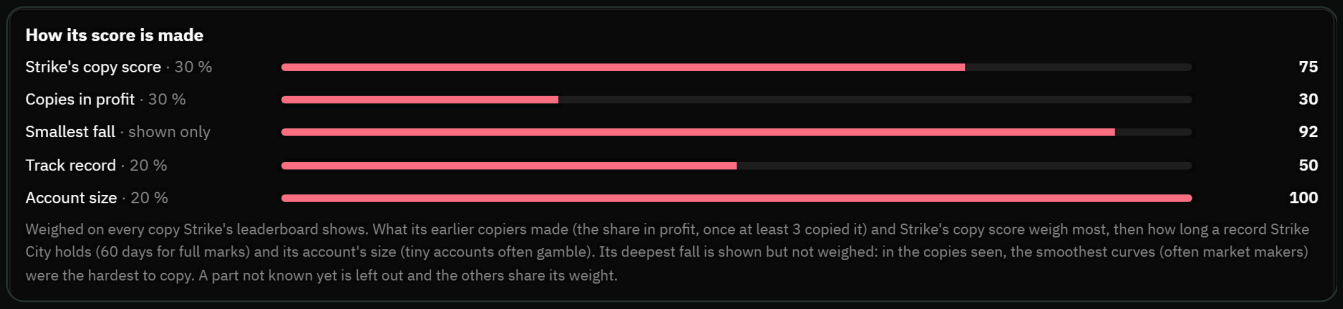

A part that cannot be known yet is left out and the others share its weight. Every trader's profile shows each part, so nobody has to take the number on trust.

How it is tested

The test replays every copy Strike's leaderboard has published. Each copy is scored only with what was known before it started, and we compare the scores of copies that ended in profit with those that did not. The collector runs this every hour and the arena shows the result as it stands. The News Tower follows the same idea: every reading is checked against Strike's own price afterwards.

At the time of writing, on 389 copies of 70 traders, the chance that a copy in profit scored higher than one at a loss is **0.59 with the Strike City score** and 0.50 with Strike's copy score alone, which is a coin toss. Among each score's top third, 24.8 % of copies ended in profit with ours and 28.7 % with Strike's, against 19.3 % for all copies. With this few traders the numbers move as copies add up, which is exactly why the test runs in public.

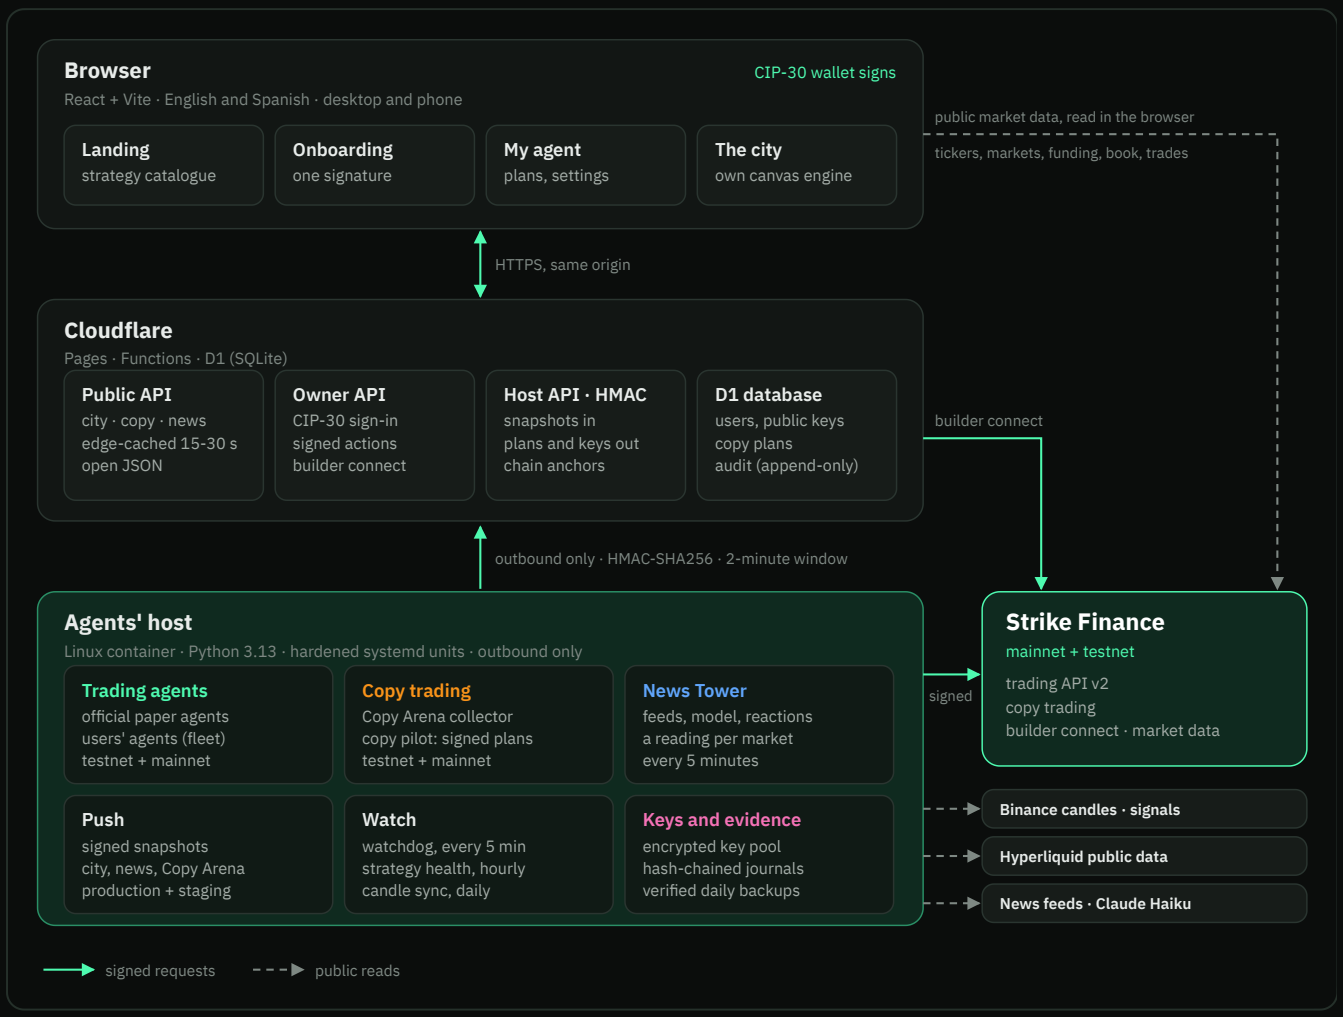

Every trader's profile shows how its score is made, part by part.

06

Under the hood

Three parts, each with one job: a site with a small serverless API, a host that runs everything that needs keys or a long-lived process, and Strike. The host never listens to the internet.

The site

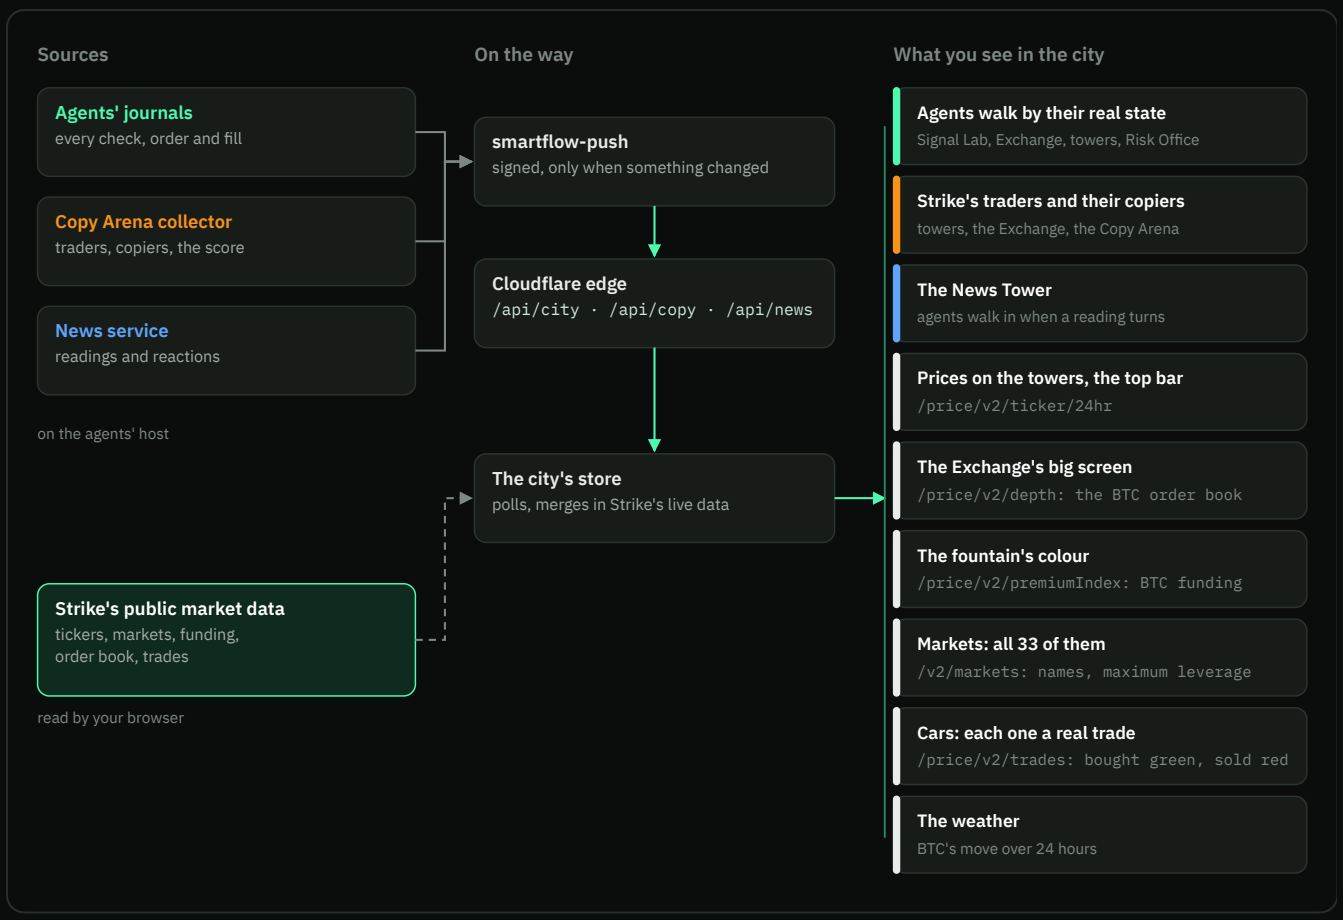

React and Vite on Cloudflare Pages. The city runs on its own canvas engine: tiles, A* paths, sprites, day and night, screens drawn from live data. Small Functions handle sessions, wallet checks, builder connect and signed plans; D1 keeps an append-only audit.

The agents' host

Python with one runtime dependency, every service under systemd as an unprivileged user with a read-only system. It never listens to the internet: it polls the site and pushes signed snapshots of the city, the news and the Copy Arena.

Where everything in the city comes from

Two roads lead into the city. The host's snapshots carry what only the host knows: each agent's journal, the copy-trading collector and the news. Strike's own market comes straight from Strike to your browser, with nothing of ours in between.

Decisions that matter

Decision	Why
One engine for backtest and live, fed candle by candle	The live signal is the backtested signal by construction, and a test guards against lookahead
Signals on Binance closes, execution on Strike's book, stops on Strike's mark price	Signal, risk and execution prices are kept apart on purpose
Deterministic `client_order_id` per trade and purpose	A retry first looks the order up, so nothing is sent twice
Private keys only on the host, public keys on the site	A compromised site cannot sign anything on Strike
Append-only, hash-chained logs, heads anchored on the site	Any claim can be answered with evidence; a rewrite would show
One strategy registry read by every part	A new strategy is data, and an unknown one is never run as another

07

Strategy and research

Smart Flow is EdgeCraft's trend-breakout strategy on the four-hour chart. It was researched with realistic costs and a protocol that decides before it looks.

How Smart Flow trades

- **Entry.** A four-hour candle with a range of at least 1 ATR and a body of at least 60 % that closes beyond the last 20 candles, on 1.5× average volume, in line with the daily structure. Breakouts born inside a very wide range are skipped; those tend to fail.
- **Protection.** A stop 1.5 ATR away goes on Strike with the entry. The size comes from that stop and the chosen risk, with room for slippage.
- **Exit.** A 4 ATR chandelier stop that follows the price on the exchange, and a close back through the 10-candle channel.
- **Pyramid.** The same signals, adding up to three entries while the trend goes on, each with its own stop and exit.

It is a trend strategy: about one trade in three wins, and the winners are several times larger than the losers, so it is judged over many trades, never a handful.

How it was researched

The engine was checked against an independent re-translation of the original script in PyneCore, with identical signals across 6,000 four-hour candles, and against TradingView's own exports. The live journals are replayed against it candle by candle. Costs include every fee, slippage, funding and Strike's minimum order. Variants were judged on development, validation and test periods plus five assets the rules never saw, with the criteria written down before looking.

Backtest, 2022-01-01 to 2026-10-18, BTC · ETH · SOL, 1 % risk	Smart Flow	Pyramid
Trades (per year)	297 (62)	482 (101)
Average result per trade (95 % CI)	+0.62 R (0.22 – 1.07)	+0.65 R (0.31 – 1.00)
Win rate · average winner	34.3 % · 3.88 R	33.8 % · 4.03 R
Profit factor	1.88	1.91
Annual return · maximum drawdown	29.7 % · 25.7 %	40.2 % · 34.0 %

Simulated results with every cost, from the same account model the agents use. Past performance, real or simulated, does not guarantee future results.

Risk, and the fee

Risk preset	Risk per trade	Available with
Conservative	0.5 %	Smart Flow and Smart Flow Pyramid
Standard (default)	1 %	Smart Flow and Smart Flow Pyramid
Assertive	2 %	Smart Flow only

On top of the preset, daily and weekly loss limits of 2 % and 5 % pause new entries while open trades keep their stop. Leverage is the lowest whose initial margin fits in 90 % of the available balance, up to 5×, and the recommended balance is 250 $ so that Strike's minimum order never gets in the way.

> **The safety hold.** Every hour each strategy's official paper agent is compared with its backtest. If live results leave the range the backtest allows, users' agents on that strategy stop opening new trades until someone has looked at it. Open trades keep their stop and their exit.

The 0.20 % builder fee came out of the research rather than the other way round: at that level the edge survives every cost, while a fee of 1 % would erase it. Users approve it explicitly in the message they sign.

08

Security and trust

Agents trade real accounts and copy plans start real copies, so trust is designed in rather than added on.

What we never hold

Users' funds stay in their own Strike accounts. Strike locks any withdrawal to the user's own wallet, and our agents never request one. API-wallet private keys are generated on the host, encrypted with AES-256-GCM and never sent anywhere; the site only knows public keys.

Consent, every time

Signing in is a CIP-30 signature over a one-time message, verified on the server down to the key belonging to the address. Every change, from a new character to a copy plan, needs a fresh signature over a message that says what it approves. Challenges are single-use, expire in five minutes and are rate-limited.

Limits that protect users

A stop with every entry, loss limits, a strategy-wide safety hold. Copies run in their own sub-account, so a copy can never touch more than what was put into it, and Strike enforces the stop-loss. A deleted agent loses its Strike connection and any copy it runs.

Evidence for every claim

The site's audit table refuses updates and deletes. On the host, every decision, Strike request, fill and balance change goes into hash-chained logs whose heads are anchored on the site every minute, with a daily backup that checks every chain.

The review before mainnet

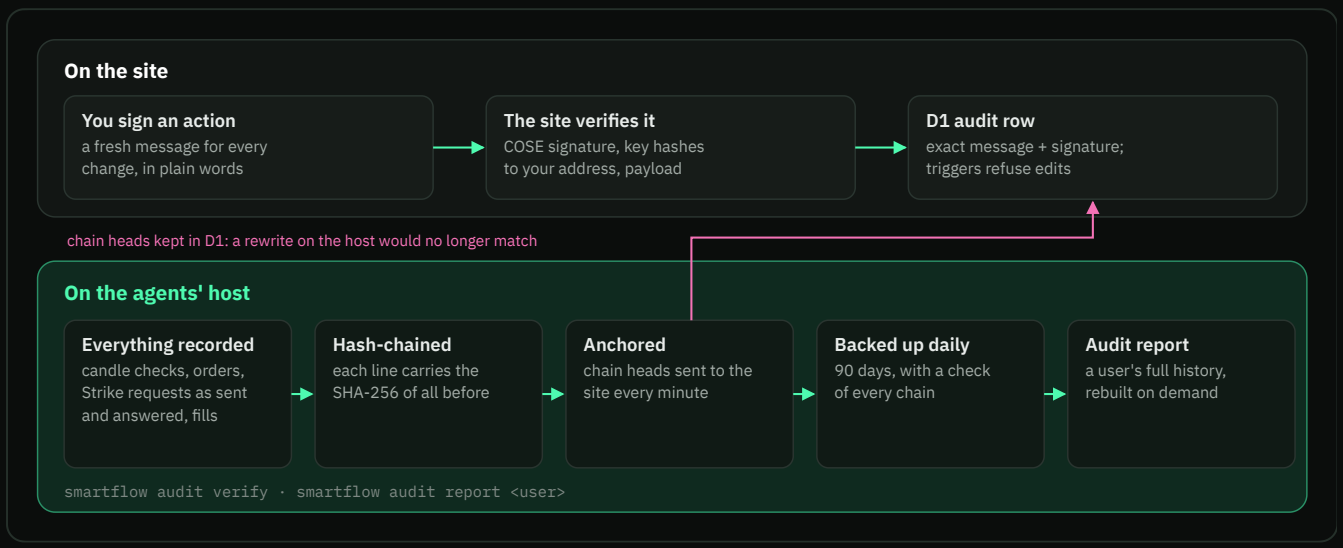

Before opening copy with your agent on mainnet we reviewed the whole path: wallet signatures, builder connect, copy plans from the page to Strike, the host's endpoints, uploads, headers, dependencies and the repository's history. There were no critical or high findings.

Area	What was checked	Result
Wallet signatures	The key hashes to the address, the address and payload are ours; cross-checked against Python references: 33 of 33 BLAKE2b vectors, 10 of 10 valid and tampered CIP-30 signatures	OK
Replay	Single-use challenges that expire in five minutes; host requests time-boxed to two minutes	OK
Keys	Private keys only on the host, encrypted; the site stores public keys	OK
Copy pilot	Stop-loss on Strike's side, an isolated sub-account per copy, a halt on refusal, idempotent requests	OK
Web	Validation on every endpoint, parameterised SQL, no HTML injection sinks, strict headers, checked uploads	OK
Dependencies and secrets	`npm audit` : 0 vulnerabilities; no secrets in the tree or its history	OK

Next hardening steps	Why
The host re-verifies each plan's signature	So that even a compromised site could not alter a plan
A stricter script policy	Once the third-party chart widget is self-hosted
Two hosts in different places	Availability that does not depend on one building

The evidence chain

Every signed action is kept on the site with its exact message, and everything the agents do is kept on the host in hash-chained logs whose heads are anchored on the site. Rewriting either side would no longer match the other.

09

Quality and QA

We treat "it works" as something to prove. Every change goes to a staging copy of the whole product on Strike testnet, is checked there in a real browser, and only then reaches production, where it is checked again.

	Production	Staging (QA)
Site	edgecraft-strikecity.pages.dev	qa.edgecraft-strikecity.pages.dev
Strike · wallets	mainnet · Cardano mainnet	testnet · Cardano Preprod
Database and services	its own D1, mainnet fleet and copy pilot	its own D1, testnet fleet and copy pilot

What gets checked

Layer	How
Logic	174 automated tests: the engine without lookahead, risk and sizing, Strike request signing and the fee header, the encrypted key pool, the copy pilot against a fake Strike, the news reading, the audit chains and the strategy registry
The strategy	Identical signals against an independent PyneCore re-translation, TradingView exports, and live journals replayed candle by candle (200 of 200 in the last full check)
Strike	API conformance checks, signed reads, order-mechanics probes on testnet, a full test-trade loop on mainnet, and a first real copy on testnet: a managed sub-account created and funded with 100 $, the copy active, checked on Strike's API
The city, in a real browser	Playwright and axe-core: every panel, button and dialog, text cut off or overflowing, the dock from 320 to 412 px, 244 checks per language; 56 checks of the map, deep links, keyboard and reduced motion; 46 checks that what the city shows matches the API and Strike, with real accounts and paper agents apart
Strike's trades as cars	The city reads Strike's trades, a car drives in, stops under the mouse and shows its trade when pressed; the top bar counts what each site should: 12 checks at desktop and phone sizes
Onboarding and copy	On staging, a test wallet creates an agent on Strike testnet, edits, hides and deletes it at desktop and phone sizes; a signed copy plan is carried out on Strike testnet and stopped
Accessibility	Zero WCAG 2.2 AA violations on every surface checked, in English and Spanish; keyboard control and text descriptions for the map

The last full run on staging, on 23 October, passed everywhere: 244 of 244 city checks in English and in Spanish, 56 of 56, 46 of 46 and 12 of 12. In production a watchdog checks the services every five minutes, strategy health runs every hour, and the audit chains are backed up and verified every night.

10

Built during the hackathon

We arrived with a working base: the Smart Flow engine and its agents, onboarding through builder connect, a first version of the city and the strategy marketplace. In three days we built everything else in this book, and all of it is live on Strike mainnet, with a staging copy on testnet.

40+
commits in three days, each one checked on staging before production

12,000+
new lines of code in Python, TypeScript and CSS

14
of the 35 Strike endpoints integrated during the hackathon: all of copy trading, and live trades

The Copy Arena: Strike's copy trading, made visible

A copy-trading leaderboard shows a trader's own return. It does not show what happened to the people who copied them, which is exactly what someone about to copy needs to know. The Copy Arena puts that in front of them.

- **A collector for the whole of Strike's copy trading.** Traders, every copy relationship and how it ended, who copies whom, open positions, and Strike's copy-trading dashboard with its six daily series. It keeps the history beyond the 30 days Strike's API returns, and it holds no keys.
- **Every trader linked by account.** A sub-account opens its main account, Strike's own names and badges are shown, and accounts that only copy others are left out, since Strike never passes their copied orders on.
- **Traders who walk the city** with the people copying them in a line behind: to the tower of their biggest position, to the Exchange when they trade, to the arena's door while they hold nothing.
- **The arena itself.** The leaderboard on an LED wall, a podium, the copiers' wall and Strike's totals, plus a live section on the landing page and the three best traders in Ranks.

The Strike City score, tested on every copy

- **A study of every published copy**, each scored only with what was known before it started. Earlier copiers' results predicted outcomes; Strike's own score alone did not; smooth curves, often market makers, were the hardest to copy.
- **A score built from that evidence**, with every part shown on each trader's profile, so nobody has to take it on trust.
- **An hourly public re-test** inside the arena. On 389 copies of 70 traders, a copy in profit outscored one at a loss 59 % of the time with our score, against 50 %, a coin toss, with Strike's alone.

Copy with your agent, on Strike's own copy trading

- **Signed plans in plain words.** One trader, or the agent choosing by your rules (a minimum score, platforms, a review period, changes a week), with the amount, a stop-loss, the leverage, markets to avoid

and an end date.

- **Run on Strike's own copy trading.** Strike creates and funds a sub-account for each copy and enforces its stop-loss; requests are idempotent; a copy Strike stopped or refused halts the plan until the owner signs again; deleting an agent stops its copy.
- **Proven, then opened.** A first real copy on Strike testnet, checked on Strike's API, on the host, in "My agent" and in the city; then the security review; then mainnet.

The News Tower: news measured on Strike

- **News a trading desk would trust.** Official and tier-one sources, filtered searches, a model on a fixed scale that keeps catalysts only, one vote per story however many outlets carry it, and every reaction measured on Strike's mark price against the market's normal move.
- **A reading per market** with what pushes it up or down, every story that counts and a scoreboard of past readings; geopolitics by region, the US macro calendar to 2027, and a warning before US releases.
- **A building you walk into.** Six floors and a lift, a marquee on the facade, your agent beside you, and agents who come to read when a market's reading turns. They never trade on it.

A city rebuilt, and alive

- **New art.** The whole map redrawn with LimeZu's licensed Modern Exteriors, every door checked to be reachable on foot, and a character creator built on LimeZu's generator.
- **Characters with a life.** A personality and a trade for every agent, the real data it reads in its bubble, and a "Meet your agent" card at the end of the onboarding.
- **Strike's trades on the streets.** Every car is a real trade on Strike mainnet; it stops under the mouse and shows its trade when pressed.
- **Everything Strike lists.** All 33 of Strike's markets in Markets, and every trader people can copy in Agents.
- **Real and paper apart.** Production counts real accounts only and ranks the paper agents on their own; staging counts both.
- **Polish where people look.** The Exchange's big screen with Strike's order book, readable signs, a top bar that never overflows, a complete Guide, and a Suggest button that takes a screenshot.

A security review before mainnet

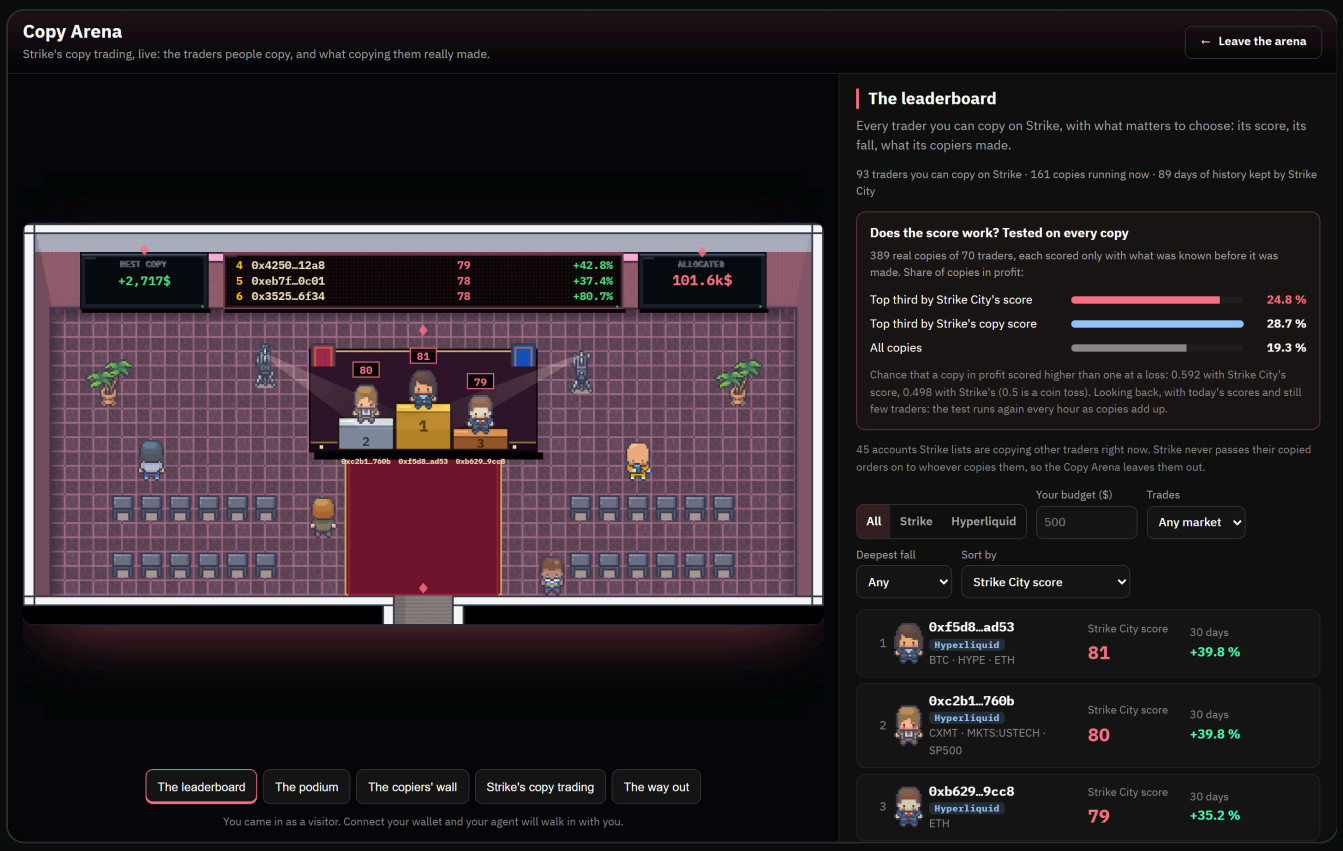

Before opening copy with your agent on mainnet we reviewed authentication and signatures, builder connect, copy plans end to end, the host's endpoints, uploads, headers, dependencies and the repository's history. There were no critical or high findings, no known vulnerabilities in production dependencies and no secrets in the code or its history, and the server's signature checks were cross-checked against independent references. The details are in chapter 8.

Verification at every step

Every change went to staging on Strike testnet first, was checked there in a real browser, then reached production and was checked again. The city's checks now walk every panel, button and dialog in both languages, and new ones cover the cars, the separation of real and paper results and every bug found in testing, at desktop and phone sizes, with accessibility audits on every surface (chapter 9).

Clean code, and this documentation

One checked bech32 decoder shared by the page and the server, typed agent voice moments and no unused code. Documentation in English with every Strike call explained, diagrams drawn from code, and this book.

Inside the Copy Arena: the leaderboard on the LED wall and the score's live test, both built during the hackathon.

11

How it meets the judging criteria

The hackathon asks for innovation, integration, utility, execution and future potential. Here is where each one shows.

Innovation and creativity	Strike's market becomes a place you can walk around, where every character is real state: an agent waiting for a candle, a trader holding a position, the people copying them right now. The city works as a live dashboard people enjoy watching, and the copy score is measured on real copies instead of guessed.
Integration with Strike	Builder connect and the builder code for onboarding and revenue, the v2 trading API for the agents, the copy-trading API for discovery, history and managed copies with their own sub-accounts, the copy-trading dashboard, and Strike's prices, book, funding, every market and every trade drawn live in the city. 35 endpoints in five areas, mainnet and testnet, all live.
Utility and impact	Only about one copy in five on Strike ends in profit, and a leaderboard number does not say who is worth copying. The Copy Arena shows what copying each trader actually did, and copy with your agent turns that choice into a signed, limited, automatic plan. For Strike, it means volume through the builder code and users who start trading in a minute.
Technical execution	Live on mainnet with a staging copy on testnet. One engine for backtest and live, keys that never leave the host, signatures verified on the server, hash-chained logs anchored off the host, 174 tests and real-browser checks with accessibility audits on every surface in two languages.
Future potential	The pieces line up with Strike's 2026 roadmap: agent vaults with a verifiable record, a creators' marketplace on top of the strategy registry, new districts for spot and real-world assets, and a social layer around everything that trades on Strike.

12

What comes next

The goal is for EdgeCraft-StrikeCity to become the social layer of Strike: the place where trading on Strike is visible, shareable and verifiable, and where people and their agents live side by side.

Strike's roadmap, and the buildings waiting for it

Strike 2026	What we add	Already in place
Vaults	Agent vaults anyone can join, with a record anyone can verify, living in the **Vault Bank**	Paper agents as public records, health checks, audit trail
Trading-tools platform	A creators' marketplace: strategies start on paper, are gated by health and share the builder fee; **Smart Flow HQ** becomes their building	Registry with creator and revenue share
Spot and RWAs	New districts, an equities quarter, News Tower floors for earnings and rates	Copied traders already hold equities and commodities
Mobile and fiat ramps	Onboarding without a crypto wallet, the city inside Strike's app, push notifications	Responsive from 320 px, alert pipeline
Cross-chain lending	Agents that use lending collateral as margin, with risk rules that understand it	Margin-aware risk engine

More we can build on what exists

- **Agents as copy-trading leads on Strike.** An agent trades its own account, so it can become a lead that anyone copies from Strike's own app, with a public, audited record.
- **Ethereum and Solana wallets.** Strike supports them already; one-signature onboarding opens to far more people.
- **Copy portfolios.** One plan spread over several traders by score and correlation, rebalanced on its review period.
- **Seasons, leagues and teams.** Monthly seasons ranked on verified, risk-adjusted results; the **Clan Hall** hosts teams.
- **Plain-language answers.** Every decision already carries its reasons; "why did my agent do that?" is a short step away.
- **Public API, widgets and a Discord bot.** The score and the city wherever Strike's community already is.
- **On-chain anchoring.** The audit chains' heads written to Cardano, so any agent's or vault's history can be verified without us.

How it scales

Users' agents, 10 to 10,000

The fleet is already a pure function of the site's list of users. It splits across workers by user, each holding a lease so no agent runs twice. Signals are computed once per market and strategy and fanned out; reads are batched, then moved to Strike's streams as they arrive; keys move into a hardware-backed key service.

The site

Cloudflare's edge already serves it. Live updates move from polling to pushed updates per district, and public snapshots move to KV storage, so a thousand viewers cost about the same as one.

The city

Beyond a few hundred characters, crowds at a building gather into counted groups that open up on zoom. The map grows by districts loaded on demand, and the canvas engine gains a WebGL path for very large crowds.

Reliability

Two hosts in different places, active and standby, with leases; an external watchdog; freshness targets for every data feed on a public status page; and a third-party audit before vaults hold other people's money.

When last measured, on 20 October, the agents' services together used about 0.3 % of one CPU core and around 420 MB of memory, which leaves a lot of room before any of this is needed.

The business

The builder fee, 0.20 % per execution on every trade a user's agent makes, grows with volume and was set so the strategy keeps its edge. Copies started by agents bring new money and copiers into Strike's copy trading. Strategy creators get a share of it. For Strike, the city and the score can become an official social and discovery layer, and an API for other builders.

Come and walk around.

The city is open, the agents are working and the Copy Arena is live. No wallet is needed to look around.
